QynBalance Guide — Enterprise Cost Intelligence

What QynBalance is

QynBalance is **Enterprise Cost Intelligence** built on **real platform data**: monitored hosts and services, enrolled agents, workspace seats, and automation activity. It analyzes infrastructure cost, capacity/license/cloud optimization, automation savings, asset utilization, and budget forecasting, and produces **advisory** optimization recommendations.

It never fabricates financial values. Monetary estimates appear *only* where the operator has configured real unit rates. When a rate is missing, QynBalance reports the real resource **count** and clearly states "**pricing unavailable**" rather than inventing a currency figure.

Backend

Piece	Path
Cost service	<code>app/Services/Platform/Cost/CostIntelligenceService.php</code>
Cost copilot	<code>app/Services/Platform/Cost/CostIntelligenceCopilot.php</code>
Adapter	<code>app/Services/QuenyxAI/Adapters/QynBalanceAiAdapter.php</code>
Controller	<code>app/Http/Controllers/Platform/CostController.php</code>
Routes	<code>routes/qynbalance-cost.php</code> (prefix <code>/api/qynbalance</code>)
Config	<code>config/cost.php</code>

Pricing configuration (honest by default)

`config/cost.php` rates are **NULL by default**. Provide real rates (from your own contracts / cloud bills) via env to unlock monetary estimates:

```
COST_CURRENCY=USD
COST_HOST_PER_MONTH= ...      COST_AGENT_PER_MONTH= ...      COST_SERVICE_PER_MONTH= ...
COST_LICENSE_PER_SEAT= ...    COST_AUTOMATION_RUN_MINUTE= ...
COST_MONTHLY_BUDGET= ...      COST_IDLE_AGENT_HOURS=72
```

Until set, the overview shows counts with `pricing_available: false` and a `configure_pricing` recommendation.

API

Base `/api/qynbalance` . Workspace-scoped, UUID-only. Overview requires `accessAi` ; the copilot requires `can_use_ai` .

Method	Endpoint	Notes
GET	/cost/overview	Infrastructure cost, license/asset/automation/capacity/cloud sections, budget forecast, recommendations.
POST	/cost/copilot	FinOps copilot narrating the deterministic cost evidence (mock-safe).

What it computes (all from real rows)

- **Infrastructure cost** — host/service/agent counts × configured rates (or "pricing unavailable").
- **License optimization** — workspace seats × seat rate (if configured).
- **Asset utilization** — hosts/services/agents, idle agents (real `last_seen_at`), services-per-host.
- **Automation savings** — successful executions and automated runtime minutes; monetized only if a per-minute rate is configured.
- **Capacity optimization** — pointer to QynSight Capacity Planning, gated on real metric samples.
- **Cloud optimization** — explicitly unavailable until a cloud billing source is connected (no invented cloud spend).
- **Budget forecast** — monthly/annual projection vs. optional configured budget (only when priced).
- **Recommendations** — idle agents, hosts without services, and "configure pricing" — each with the real evidence behind it. Advisory only; never auto-applied.

UI

`/app/workspaces/:id/qynbalance/cost` — cost table (counts + monetary where priced), a clear "pricing unavailable" banner when rates are unset, recommendations, and a Cost Intelligence copilot.
