Platform Operations Guide

Quenyx vOPS HUB — v1.0.0 · Document v1.0

Document Version	1.0
Software Version	v1.0.0
Applies To	Quenyx vOPS HUB v1.0.0 — Sprint 25
Classification	Internal
Owner	Platform Engineering / SRE
Status	Released
Document Type	Operations guide

Table of Contents

- | Purpose
- | Platform Health
- | Registries (the extensibility seams)
- | Day-2 runbook
- | Security envelope (every Sprint 25 endpoint)

Platform Operations Guide

Purpose

How to operate the Quenyx vOPS HUB platform itself in production: the registries that make it extensible, the Platform Health surface that watches it, and the day-2 runbook for the Sprint 25 services.

Platform Health

GET `/api/qynva/health` (requires `administerAi`) → `app/Services/Platform/Health/PlatformHealthService.php` . Returns an overall status plus per-area status:

Area	What it checks
AI Platform	provider availability / mock fallback, AI Adapter Registry populated
Automation Platform	Automation Adapter + Action registries populated
Knowledge Platform	Knowledge Source Registry populated
Search	Enterprise Search reachable
Registries	AI / automation / action / knowledge registry counts
Provider health	configured AI provider reachability (honest when in mock mode)
Event Bus	subscriber count + recent event ring
Queues	queue connection + pending/failed jobs (honest if not inspectable)
Background jobs	scheduler/worker liveness signals

Status bands: `operational` , `degraded` , `down` . Surfaced in the UI at `/qynva/health` .

Registries (the extensibility seams)

All four follow one pattern: register one line in `AppServiceProvider::boot()` , no module branching.

Registry	Add a...
<code>AIModuleAdapterRegistry</code>	module AI adapter (capabilities + context)
<code>AutomationAdapterRegistry</code>	execution adapter (SSH, REST, ...)
<code>ActionRegistry</code>	automation action
<code>KnowledgeSourceRegistry</code>	knowledge source provider
<code>PlatformEventBus</code>	event subscriber (<code>subscribe()</code>)

Day-2 runbook

- **AI shows `ai_enabled: false` everywhere** → provider not configured; platform runs on the deterministic mock. Configure a provider in AI settings; evidence is always real regardless.
- **QynBalance shows "pricing unavailable"** → expected until `config/cost.php` rates are set via env. This is correct, honest behavior — not a bug.
- **A subscriber throws** → publishing is unaffected (failures are caught + logged). Inspect the log and `GET /api/qynva/events`.
- **Health area `degraded` / `down`** → open `/qynva/health`, read the area's reason, follow the matching registry/queue/provider check above.
- **Event Bus async migration** → replace the `dispatch()` body in `PlatformEventBus` with a queued job; publishers and subscribers need no changes.

Security envelope (every Sprint 25 endpoint)

Workspace resolution → module entitlement → RBAC policy (`accessAi` / `can_use_ai` / `administerAi`) → audit. UUID-only addressing and workspace isolation are enforced platform-wide.
